Definition

An *algebraic number field* is a finite algebraic extension of the rational field.

Definition

An *algebraic function field* is an extension field F containing a field k such that F is a finite algebraic extension of a rational function field $k(t)$ for some element $t \in F$ which is transcendental over k .

Relative Extensions

Definition

The *Galois group*, $\text{Gal}(f)$, of a polynomial f over a field F is the automorphism group of the splitting field of f over F .

- $\text{Gal}(f)$ is a group of permutations of the roots of f .
- All permutations of n roots are in S_n so $\text{Gal}(f) \subseteq S_n$ and is often S_n .

Definition

The *Galois group*, $\text{Gal}(f)$, of a polynomial f over a field F is the automorphism group of the splitting field of f over F .

- $\text{Gal}(f)$ is a group of permutations of the roots of f .
- All permutations of n roots are in S_n so $\text{Gal}(f) \subseteq S_n$ and is often S_n .
- Previous algorithms for computing Galois groups (except Hulpke [Hul99]) all restricted the degrees of the polynomials they accepted as input.
- Previous algorithms and their degree restrictions :
 - ▶ Geißler [Gei03] (23),
 - ▶ Geißler and Klüners [GK00] (15),
 - ▶ Eichenlaub [Eic96] and Oliver (11),
 - ▶ Absolute resolvent methods (11).
- Our approach following [FK14] is based on that of Stauduhar [Sta73].

First Example

Let $f(x) = x^4 - 4x^2 - 5 = (x^2 + 1)(x^2 - 5)$.

The Galois group of f is a subgroup of S_4 .

Since the 4 roots of f can be grouped into pairs, a number of these 24 permutations in S_4 do not correspond to automorphisms of $\mathbb{Q}(i, \sqrt{5})$.

The Galois group of f has 4 elements, generated by the permutations

- $i \mapsto -i$ and
- $\sqrt{5} \mapsto -\sqrt{5}$

both of order 2.

The splitting field of f , $\mathbb{Q}(i, \sqrt{5})$, has degree 4 over \mathbb{Q} .

Second example

Let $f(x) = x^4 - 2 = (x^2 - \sqrt{2})(x^2 - i^2\sqrt{2})$.

The 4 roots of f are $\sqrt[4]{2}, i\sqrt[4]{2}, -\sqrt[4]{2}$ and $-i\sqrt[4]{2}$.

The Galois group of f is again a subgroup of S_4 but this time the symmetries between the roots are different.

The Galois group of f has 8 elements, generated by the permutations

- $\sqrt[4]{2} \mapsto i\sqrt[4]{2}$ of order 4 and
- $i\sqrt[4]{2} \mapsto -i\sqrt[4]{2}$ of order 2.

The splitting field of f , $\mathbb{Q}(\sqrt[4]{2}, i)$, has degree 8 over \mathbb{Q} .

Third Example

Let $f = x^4 + x^3 - x^2 + x + 6$ which factors as a linear and a cubic (f_3) over $K = \mathbb{Q}[x]/f$ and as 2 linears and a quadratic over $K[x]/f_3(x)$. There are no other algebraic equations satisfied by the roots of f and hence there is no symmetry between these 4 roots.

The Galois group of f is S_4 and is generated by the permutations

- $\alpha \mapsto \beta, \beta \mapsto \gamma, \gamma \mapsto \delta, \delta \mapsto \alpha$ of order 4 and
- $\alpha \mapsto \beta$ of order 2

where α, β, γ and δ are the roots of f in some order.

The splitting field of f has degree 24 over \mathbb{Q} .

Definition

A polynomial $I(x_1, \dots, x_n) \in R[x_1, \dots, x_n]$ such that $I^\tau = I$ for all $\tau \in H$ for some group $H \subseteq S_n$ is said to be *H-invariant*.

Definition

A *H-invariant* polynomial $I(x_1, \dots, x_n) \in R[x_1, \dots, x_n]$ is a *G-relative H-invariant* polynomial if $I^\tau \neq I$ for all $\tau \in G \setminus H$, $H \subset G \subseteq S_n$, that is, for the stabiliser in G we have $\text{Stab}_G I = H$.

Definition

For a G -relative H -invariant polynomial I we can compute a G -relative H -invariant *resolvent polynomial*

$$Q_{(G,H)}(y) = \prod_{\tau \in G//H} (y - I^\tau(x_1, \dots, x_n)),$$

where $G//H$ denotes a system of representatives for the right cosets $H\tau$ of G/H . If $G = S_n$ then we call Q an *absolute resolvent*, otherwise we call Q a *relative resolvent*.

Definition

Let G be a transitive permutation group acting on a finite set Ω . A subset $\emptyset \neq \Delta \subset \Omega$ is called a *block* if $\Delta \cap \Delta^\sigma \in \{\emptyset, \Delta\}$ for all $\sigma \in G$.

The orbit of a block Δ under G is called a *block system*.

The blocks we use will be subsets of $\Omega = \{\text{roots of } f\}$.

Theorem (Generalization of [Sta73], Theorem 5)

Let $f(x)$ be a separable polynomial of degree n over a field F . Let $\alpha_1, \dots, \alpha_n$ be a fixed ordering of the roots of $f(x)$ in S_f . Suppose G is a subgroup of S_n and suppose that with respect to the given ordering of the roots, the Galois group $\text{Gal}(f)$ of $f(x)$ is a subgroup of G . Let H be a subgroup of G and $I(x_1, \dots, x_n) \in R[x_1, \dots, x_n]$ be a G -relative H -invariant polynomial. Let τ_1, \dots, τ_k be representatives for the right cosets of H in G . For all i , $I^{\tau_i}(\alpha_1, \dots, \alpha_n)$ is a root of the resolvent polynomial

$$Q_{(G,H)}(y) = \prod_{i=1}^k (y - I^{\tau_i}(\alpha_1, \dots, \alpha_n)) \in F[y].$$

Assume $I^{\tau_i}(\alpha_1, \dots, \alpha_n)$ is not a repeated root of $Q_{(G,H)}(y)$. Then $\text{Gal}(f) \subseteq \tau_i H \tau_i^{-1}$ iff $I^{\tau_i}(\alpha_1, \dots, \alpha_n) \in F$.

Very roughly,

$$I(\alpha_1, \dots, \alpha_n) \in F \Rightarrow \sigma(I) = I, \sigma \in \text{Gal}(f) \Rightarrow \text{Gal}(f) \cap G \subseteq H \Rightarrow \\ \text{Gal}(f) \subseteq H$$

$$\sigma \in \text{Gal}(f) \subset H \Rightarrow \sigma(I) = I \Rightarrow I(\alpha_1, \dots, \alpha_n) \in F$$

When $\text{Gal}(f) \subseteq H$, the symmetries between the roots contribute to $I(\alpha_1, \dots, \alpha_n) \in F$.

Examples

Invariants for the maximal subgroups of S_4 are :

- 1 x_1 (non transitive)
- 2 $((x_1 + x_2)^2 + (x_3 + x_4)^2)$
 - ▶ $(-\sqrt[4]{2} + \sqrt[4]{2})^2 + (-i\sqrt[4]{2} + i\sqrt[4]{2})^2 = 0 \in \mathbb{Q}$
 - ▶ $(-i + i)^2 + (-\sqrt{5} + \sqrt{5})^2 = 0 \in \mathbb{Q}$
- 3 $((x_2 - x_4) * (x_3 - x_4)) * (((x_1 - x_3) * (x_1 - x_2)) * ((x_1 - x_4) * (x_2 - x_3)))$

```
> for x in MaximalSubgroups(Sym(4)) do
for> for y in Sym(4) do
for|for> Evaluate(RelativeInvariant(Sym(4), x'subgroup),
      PermuteSequence([x[1] : x in Roots(f, KKK)], y)) in Q;
for|for> end for;
for> end for;
false false false false false false false ...
```

The Fieker–Klüners Algorithm

Algorithm (Computation of the Galois group of a polynomial)

Input : a monic, integral, separable polynomial f of degree n over $F = \mathbb{Q}, \mathbb{F}_q(t), \mathbb{Q}(t)$ or an extension thereof.

- 1 *Compute a splitting field S_f for f over a completion of F .*
- 2 *Find a group $G \subseteq S_n$ which contains $\text{Gal}(f)$*
- 3 *While G has maximal subgroups which could contain $\text{Gal}(f)$*
 - 1 *For each maximal subgroup H of G , compute a G -relative H -invariant polynomial I_H .*
 - 2 *For a cheap maximal subgroup H of G (Stauduhar)*
 - 1 *Compute the precision m needed in the roots of f and the roots of f in S_f to precision m .*
 - 2 *for the representatives $\tau \in G//H$ of cosets of H in G , evaluate I_H^τ at the roots of f . Decide whether this is the image of an element of F in S_f . If so $\text{Gal}(f) \subseteq \tau H \tau^{-1}$ and restart the loop (3) with $G = \tau H \tau^{-1}$.*
- 4 *$\text{Gal}(f)$ is G*

Setup for Galois group computation

The algorithm was stated in full generality. Here we detail the specific differences for characteristic p function fields.

① Splitting Field $S_{f,p}$:

- ▶ when F is a number field can use the complex field or a p -adic field.
- ▶ when F is a function field can use a series ring as an analogue of a p -adic field.

These p -adic completions have better precision management than the complex field.

- ## ② We can compute a smaller starting group using the subfields of $F[x]/f$. For function fields with characteristic p these can now be computed using [vHKN11]. This may save a number of “descent” steps (3) from S_n – a substantial gain for some groups.

Invariants (Step 3.1)

- When F has characteristic 0 invariants in $\mathbb{Z}[X_1, \dots, X_n]$ can be used.
- When F is a characteristic p function field invariants in $\mathbb{F}_q[t][X_1, \dots, X_n]$, must be used.
- The general $I(\underline{X}) = \sum_{\tau \in H} (\prod_{i=1}^{n-1} X_i^{\tau})^\tau$ is expensive to use due to many multiplications.
- When $G \not\leq A_n, H < A_n, I(\underline{X}) = \prod_{1 \leq k < j \leq n} (X_k - X_j)$ (SqrtDisc) is sometimes better but I is G -invariant in characteristic 2.
- In characteristic 2 when $G \not\leq A_n, H < A_n$ we can use

$$I(\underline{X}) = \prod_{1 \leq k < j \leq n} (X_k + \bar{u}X_j) = I_1 + \bar{u}I_2 \quad ([Els13] \text{ SqrtDisc})$$

where I_1 and I_2 are also G -relative H -invariant and \bar{u} is the image of u in $\mathbb{F}_2[u]/\langle u^2 - 1 \rangle$, also $I(\underline{X}) = \sum_{1 \leq k < j \leq n} X_k \frac{\prod_{1 \leq r < s \leq n} (X_r + X_s)}{X_k + X_j}$ although the former is the most efficient.

An invariant in characteristic 2

$s_1 \equiv s_m$ When $G \subseteq S_{n/l} \wr_{\Gamma} S_l$ for some $l|n$, $\Gamma = \{1, \dots, l\}$ there is a subgroup H with the same block systems as G such that

$$I(\underline{X}) = \prod_{b \in B} E(\{X_j : j \in b\}) \quad (s_m)$$

where E is the efficient [Els13] SqrtDisc invariant and

$$I(\underline{X}) = \sum_{b \in B} \left(\sum_{j, j' \in b, j < j'} \frac{X_j}{X_j + X_{j'}} \right) \quad (s_1)$$

are both G -relative H -invariant where $B = \{b_i\}_{1 \leq i \leq l}$ is a block system of both G and H , $\#b_i = n/l$.

Other invariants in characteristic $p \neq 2$

When the characteristic of F is not 2, the following gives polynomials $I(\underline{X}) = I(X_1, \dots, X_n)$ which are G -relative H -invariant polynomials for some maximal subgroup H when G satisfies the conditions given.

SqrtDisc, [Gei03] Algorithm 6.24 Step 1 When $G \not\leq A_n, H < A_n$

$$I(\underline{X}) = \prod_{1 \leq i < j \leq n} (X_i - X_j)$$

D, [Gei03] Satz 6.8, Algorithm 6.24 Step 3.2.2 When G is a subgroup of $S_{n/l} \wr_{\Gamma} S_l$ for some $l|n, \Gamma = \{1, \dots, l\}, H$ is a subgroup of $S_{n/l} \wr_{\Gamma} A_l$ having the same block systems as G ,

$$I(\underline{X}) = \prod_{1 \leq i < j \leq \#B} (y_i - y_j)$$

where $y_j = \sum_{j' \in b_j} X_{j'}$ and B is a block system of both G and $H, |B| = l, \#b_j = n/l, b_j \in B$.

Other invariants

Let H be a maximal subgroup of $G \subseteq S_n$. Then for all characteristics of F , the following gives polynomials $I(\underline{X}) = I(X_1, \dots, X_n)$ which are G -relative H -invariant polynomials when G and H satisfy the conditions given.

Intransitive, [FK14] Lemma 5.1 When H is an intransitive group and there is an orbit \mathcal{O} of H which is not invariant under G ,

$$I(\underline{X}) = \sum_{i \in \mathcal{O}} X_i.$$

ProdSum, [Gei03] Algorithm 6.24 Step 3.1, [FK14] Lemma 5.3, [Els14b]

When there exists a block system B of H which is not a block system of G ,

$$I(\underline{X}) = \prod_{b \in B} \left(\sum_{i \in b} X_i \right) \text{ and } I(\underline{X}) = \sum_{b \in B} \left(\sum_{i \in b} X_i \right)^e$$

where $e = 2$ unless $p = 2$ then $e = 3$.

Theorem ([Fie09], [Gei03] Satz 6.21, Algorithm 6.24 Step 5, [FK14] Lemma 5.8)

Let $H_1, H_2 \subset G \subseteq S_n$ be two distinct subgroups of index 2 in G with G -relative H_i -invariants l_i , $G/H_i = \{\text{Id}, \tau_i\}$. Then, when the characteristic of F is 2,

$$l(\underline{X}) = \begin{cases} l_1 + l_2, & \text{if } l_i^{\tau_i} = l_i + 1 \\ l_1 l_2^{\tau_2} + l_2 l_1^{\tau_1} & \text{otherwise} \end{cases}$$

is a G -relative H -invariant where $H = \langle H_1 \cap H_2, \tau_1 \tau_2 \rangle$ and when the characteristic of F is not 2

$$l(\underline{X}) = l_1 l_2, \text{ if } l_i^{\tau_i} = -l_i$$

$$l(\underline{X}) = (l_1 - l_1^{\tau_1})(l_2 - l_2^{\tau_2}) \text{ otherwise}$$

is a G -relative H -invariant where $H = (H_1 \cap H_2) \cup ((G \setminus H_1) \cap (G \setminus H_2))$.

Computing Fixed Fields of Subgroups

Algorithm (Compute a Fixed Field of a subgroup ([FK06]))

Given a subgroup $U \subseteq G = \text{Gal}(f)$ compute the subfield of the splitting field of f fixed by U .

- 1 Compute a G -relative U -invariant polynomial I and the right transversal $G//U$.
- 2 Compute a bound B on the evaluation of I at the roots $\{r_i\}_{i=1}^n$ and compute the roots to a precision that allows the bound B to be used.
- 3 Compute the polynomial g with roots $\{I^\tau(r_1, \dots, r_n) : \tau \in G//U\}$.
- 4 Map the coefficients of g back to the coefficient ring of f using B . The resulting polynomial defines the fixed field of U .

$$\beta = I(r_1, \dots, r_n) \rightarrow g(\beta) = 0,$$

$$\sigma \in U \rightarrow \sigma(\beta) = I^\sigma(r_1, \dots, r_n) = I(r_1, \dots, r_n) = \beta.$$

Computations of a Splitting Field using Fixed Fields

Algorithm (Compute a Splitting Field using a fixed field of the Galois group)

Given a polynomial f over F compute the splitting field of f over F .

- 1 Compute $G = \text{Gal}(f)$.
- 2 Compute the fixed field of the subgroup $\{\text{Id}(G)\}$.

Example of a splitting field computed using a fixed field

```
> tt := Cputime(); G, _, S := GaloisGroup(f); G;

Algorithm (Compute a Splitting Field as a tower of extensions using a Galois group ([FK06]))

Given a polynomial $f \in F[x]$ of degree n , where F is \mathbb{Q} , $\mathbb{Q}(\alpha)$ or $\mathbb{F}_q(t)$, compute a splitting field for f as a tower of extensions of F .

- 1 Compute $G = \text{Gal}(f)$. If G is trivial then F is a splitting field.
- 2 Compute a descending chain C of subgroups C_k of G as stabilizers and matching invariants I_k starting with $C_0 = G$.
- 3 for each $C_k \neq G$ in the chain C find the minimal polynomial of a relative primitive element for the next extension F_k by
 - 1 Compute the right transversal $T_k = C_{k-1} // C_k$.
 - 2 Compute the p -adic roots of f to enough precision and transform them.
 - 3 Compute the coefficients of the absolute basis for the power sums of evaluations of I_k at the transformed roots permuted by each permutation in $\tau \in T_k$ multiplied by each permutation π in $\prod_{j < k} T_j$.
 - 4 Map these coefficients back to F and so gain the power sums in F_{k-1} .
 - 5 The monic polynomial whose other coefficients are elementary symmetric functions in the power sums defines F_k .

Problems in Characteristic p

The elementary symmetric functions using power sums p_m are

$$e_l(x_i) = \sum_{m=1}^l (-1)^{m-1} e_{l-m}(x_i) p_m(x_i), 1 \leq l \leq \#T_k$$

Problems in Characteristic p

The elementary symmetric functions using power sums p_m are

$$le_l(x_i) = \sum_{m=1}^l (-1)^{m-1} e_{l-m}(x_i) p_m(x_i), 1 \leq l \leq \#T_k$$

What if $\#T_k \geq \text{char}(F)$ so that $l \equiv 0 \pmod{\text{char}(F)}$ occurs?

Problems in Characteristic p

The elementary symmetric functions using power sums p_m are

$$le_l(x_i) = \sum_{m=1}^l (-1)^{m-1} e_{l-m}(x_i) p_m(x_i), 1 \leq l \leq \#T_k$$

What if $\#T_k \geq \text{char}(F)$ so that $l \equiv 0 \pmod{\text{char}(F)}$ occurs?

Can we compute the coefficients of

$$\prod_{\tau \in T_k} (x - l^\tau(r_1, \dots, r_n))$$

without directly using elementary symmetric functions?

Example of a splitting field computed as a tower

```
> time GSF := GaloisSplittingField(f : Roots := false);
Time: 0.750
> Fqta<aa> := CoefficientField(GSF);

Solution of a polynomial by radicals

Algorithm (Solve a polynomial by radicals using its Galois group)

Given a polynomial f over F compute a tower of radical extensions over which f splits.

- 1 *Compute $G = \text{Gal}(f)$ and check G is solvable.*
- 2 *Determine which roots of unity are needed and compute the Galois group G of the product of f and the associated cyclotomic polynomials divided by their GCD with f .*
- 3 *Compute a chain C of subgroups, starting with G , then those which stabilize an increasing number of roots of unity and ending with the rest of the composition series.*
- 4 *Compute the tower of cyclic fields from C using the Splitting Field Algorithm Step 3.*
- 5 *Transform cyclic extensions to radical extensions.*

Cyclic extension to radical extension

degree 2 map α , a zero of $x^2 + a_1x + a_0$, to $\alpha + a_1/2$, a zero of $x^2 - a_0/4$

degree > 2 $\sum_i \zeta^i \sigma^{(n-i)}(a)$, is a primitive element such that its degree-th power is in F_{k-1} where ζ is a root of unity and σ generates the automorphism group of the cyclic extension¹.

¹B. L. van der Waerden, *Modern algebra*, Frederick Ungar Publishing Co., 1966.

Automorphisms

- Used Galois group when extension was at the top
- Can always use Galois group since each extension in the tower is normal even if the extension is not normal as an extension of the coefficient ring of the polynomial
- Can get the Galois group for free from the Galois correspondence as the cyclic group of order p which is the quotient of two subgroups of the Galois group.
- Even easier than that : all non-identity elements of a cyclic group of order p generate the group so can use any automorphism, that is, map the generator of the cyclic but non radical extension to any one of the roots of the cyclic defining polynomial.
- So at least one of the three problems is solved!

Degree = Characteristic extensions

In characteristic p :

- $x^p - a$ is inseparable : only has one distinct root, not p , derivative 0
- In a cyclic degree p extension F_k/F_{k-1} there exists β such that $\beta^p - \beta \in F_{k-1}$.²
- $x^p - x - a = \prod_{i=1}^{p-1} (x - (\beta + i))$ defines an Artin–Schreier extension.
- It is customary to use a wider definition of solvability by radicals in prime characteristic.³
- In prime characteristic allow adjoining of elements α such that $\alpha^p - \alpha$ lies in a given field.⁴

²H. Stichtenoth, *Algebraic function fields and codes*, Springer, 1993, A13

³I. Stewart, *Galois Theory*, Chapman and Hall, 1989, p 129

⁴I. Stewart, *Galois Theory*, Chapman and Hall, 1989, Remark p 147

How to compute a such that $x^p - x + a$ defines the cyclic extension?

S. Lang, Algebra, Springer, 2002, Theorems 6.3 and 6.4 give us

$$\alpha = 1/\mathrm{Tr}(\theta) \sum_{i=1}^{p-1} i\sigma^i(\theta)$$

where $\mathrm{Tr}(\theta) \neq 0$, so

$$a = \alpha^p - \alpha$$

Two problems solved!

Example of a solution of polynomial by radicals

```
> time S := SolveByRadicals(f); CS<cs> := CoefficientRing(S);  
Time: 0.940
```

```
> _<t> := CoefficientRing(CS); S:Maximal;
```

```
S
```

```
|          $.1^2 + 100*t
```

```
CS<cs>
```

```
|          $.1^3 + 8*t + 8
```

```
|
```

Univariate rational function field over $GF(101^2)$

Variables: t

```
> DefiningPolynomial(ConstantField(S));
```

```
t^2 + 26
```

```
> _<w> := ConstantField(S); Roots(f, S);
```

```
[ <S.1 + (51*w + 25)*cs, 1>, <100*S.1 + (51*w + 25)*cs, 1>,  
  <S.1 + (50*w + 25)*cs, 1>, <100*S.1 + (50*w + 25)*cs, 1>,  
  <S.1 + 51*cs, 1>, <100*S.1 + 51*cs, 1> ]
```

An example with a degree characteristic extension

```
> f := x^5 + x^4 + t; G := GaloisGroup(f);
> TransitiveGroupDescription(G); IsSoluble(G);
F(5) = 5:4                                     true
> S := SolveByRadicals(f); CS<cs> := CoefficientRing(S);
> CCS<ccs> := CoefficientRing(CS);
> S:Maximal;
      S
      |
      |                                     $.1^5 + 4*$.1 + 2/t^2*ccs*cs
      |                                     CS<cs>
      |                                     |
      |                                     |                                     $.1^2 + 2*ccs
      |                                     |                                     CCS<ccs>
      |                                     |                                     |
      |                                     |                                     |                                     x^2 + 4*t^3
Univariate rational function field over GF(5)
Variables: t
```

And the radical roots

```
> Roots(f, S);  
[  <S.1^4 + S.1^3 + S.1^2 + S.1, 1>,  
   <S.1^4 + 3*S.1^3 + 4*S.1^2 + 2*S.1, 1>,  
   <S.1^4 + 2*S.1^3 + 4*S.1^2 + 3*S.1, 1>,  
   <S.1^4 + 4*S.1^3 + S.1^2 + 4*S.1, 1>,  
   <S.1^4 + 4, 1>  
]  
> Roots(f, FunctionField(f));
